Th

Empirics 000000000 Reconciliation with Prior Work

Conclusion

## Neighborhood Choice With or Without Racial Spillovers

Builds on Bayer et al. (2007) and Almagro et al. (2023)

- Standard discrete location choice model:

$$m{v}_{ji} = -lpha_{r(i)} \log(m{p}_j) + \sum_k m{w}_{jk} m{s}'_k m{eta}_{r(i)} + \eta_{r(i)j} + \epsilon_{ji}$$

- Nested via spatial weights:
  - Bounded Neighborhood  $w_{jk} = \mathbb{1}\{j = k\}$
  - Spatial Proximity  $w_{jk} = \frac{\exp(-\kappa d_{jk})}{\sum_{l} \exp(-\kappa d_{il})}$
- Asymmetric Homophily: Strong for Whites, Weak (or Zero) for Minorities

Segregation & Locus of Racial Change (Davis, Easton, Thies)

Introduction

Theory

Empirics

## **Contrasting Predictions of the Models**

	Bounded Neighborhood	Spatial Proximity
Racial Clusters	Random	Strong Clustering
Racial composition at cluster boundaries	Precipitous Jump	Smooth Decrease
Price gradients at cluster boundaries	Precipitous Jump	Smooth Increase
Locus of Racial Change	Random	At Boundaries of Clusters

Empirics

Reconciliation with Prior Work

Conclusion

## **Data Description**

- Neighborhood Change Database (NCDB)
  - Same dataset as Card, Mas, Rothstein (2008)
  - Panel of census tract demographics from 1970-2000 on 2000 tract boundaries
  - Metropolitan Statistical Areas (MSAs) using 1999 definitions
  - 35,000+ tracts, 104+ MSAs across all three decades
- Longitudinal Tract Database (LTDB)
  - Tract-level housing price data
- U.S. Census Tract-level Shapefiles
  - Geographic boundaries for 2000 tracts and MSAs
- Caveat: Just Two Groups
  - White Non-Hispanic vs. Minority
  - Robustness: Black (Non-Hispanic) vs. Non-Black

## White Share Declines Concentrated in Boundary Tracts - All MSAs

## The Majority of Declines is Connected to the Boundary - All MSAs

## Taking Stock

- Results strongly support spatial proximity model, most importantly:
  - Importance of racial clusters
  - Change at the boundary of racial clusters
- Strongly at odds with Card, Mas, Rothstein (2008) on the locus of racial change
  - "Taken together, [our] results are not consistent with the predictions of the expanding ghetto model. Tipping effects are, if anything, strongest far from the existing ghetto." (p. 205)
- Reconciliation required

## Partial Equilibrium Theory in Card et al. (2008)

Motivation for Reduced Form Analysis

## Partial Equilibrium Theory in Card et al. (2008)

Motivation for Reduced Form Analysis

## Empirical Approach in Card et al. (2008)

- Split census data into training (2/3) and testing (1/3)
- Use *training* to find candidate tipping points on MSA-level ( $s_{cm}^{*}$ )
- Suggestive evidence of tipping from discontinuous local regressions on MSA-level
- Formal significance tests using global quartic polynomial  $f(\cdot)$  on pooled data

$$y_{c(j)j} = f(s_{jm}) + \mathbb{1}\{s_{jm} > s_{cm}^*\}\beta + X_{jt}\gamma + \alpha_c + \epsilon_{jt}$$

- $y = \Delta$ White Pop<sub>t+1</sub>/Total Pop<sub>t</sub>
- Coefficient of interest  $\beta$

- MSA-fixed effect *α*<sub>c</sub>
- Controls X<sub>jt</sub>

Reconciliation with Prior Work

Conclusion

# Spatial Stratification for Estimation

- Approach parallels Card et al. (2008):
  - Global polynomial regression
  - Pool MSAs using fixed effects and controls
- Split sample:
  - Urban  $\geq$  1,000 people per  $km^2$
  - Suburban < 1,000 people per  $km^2$
- Split urban
  - More Exposed I ≤ 2 (Spatial proximity)
  - Less Exposed / > 2 (Bounded neighborhood)

## All MSA Regression Results, Levels

## All MSA Regression Results, Urban vs. Suburban, Shares

### All MSA Regression Results, Shares

## Conclusions

Strong support for Schelling's spatial proximity model:

- Importance of racial clusters
- Racial change happens at the boundary of clusters

Tipping framework seemed to give strong results, but

- Results actually highly spatial
- Prior tipping results largely driven by White entry (not exit!) in suburbs
- White exit is concentrated at boundaries of clusters

#### A spatial approach to understanding racial neighborhood change is crucial

# Parameters for Simulation • Back

Symmetric:

- Price sensitivity  $\alpha_m = \alpha_w = 20$ 

Asymmetric:

- Group sizes:  $N_m = 30$  and  $N_w = 70$
- Spatial weights
  - No spillovers (100% own location):

$$w_{jk} = \mathbb{1}\{j = k\}$$

- Spillovers (45% own, 45% neighbors, 10% remaining locations):

$$w_{jk} = \exp(-\kappa d_{jk}) / \sum_{l} \exp(-\kappa d_{jl})$$
 with  $\kappa = 15$ 

- White racial preferences imply semi-elasticity: 1 pp increase in Minority share is compensated with 0.4% price decrease

- Racial preferences  $\beta_m = 0$  vs.  $\beta_w = 8$

## Simulations and Equilibrium Solver

Solver mimics frictionless dynamic and myopic movement of households: (similar to Almagro et al., 2023)

- 1. Randomly initiate Minority shares:  $s_i^{(0)} \stackrel{iid}{\sim} \text{Uniform}(0, 1)$ .
- 2. Given  $s_j^{(t)}$ , find prices  $p_j^{(t)}$  that equilibrate aggregate demand  $D_j$  and housing supply  $H_j$  at each location. (Contraction Mapping)
- 3. Given  $s_i^{(t)}$  and  $p_j^{(t)}$ , update racial compositions  $s_i^{(t+1)}$ .
- 4. Repeat steps 2 and 3 until convergence.

#### Gelman and Imbens (2018) Provide a Helpful Title

#### "Why High-Order Polynomials Should Not Be Used in Regression Discontinuity Designs"

It is common in regression discontinuity analysis to control for third, fourth, or higher-degree polynomials of the forcing variable. There appears to be a perception that such methods are theoretically justified, even though they can lead to evidently nonsensical results. We argue that controlling for global high-order polynomials in regression discontinuity analysis is a flawed approach with three major problems: it leads to noisy estimates, sensitivity to the degree of the polynomial, and poor coverage of confidence intervals. We recommend researchers instead use estimators based on local linear or quadratic polynomials or other smooth functions.
